twig/twig files during the compilation step. Added support for sub-string replacement on the "trim" parameter of the Twig filter. Compiling Twig files ----- To compile the Twig code, you can use the phlyRest twig-compiler found in the "phlyRest" package. \$ twig-compiler --path --output. Once the compiler is done, you can run the files using the "twig" command \$ twig example.html
Example output ----- For convenience, the "trim" Twig filter is included in the "helpers" namespace. You can use this by name like this: "twig {% autoescape false %} {{ "Hello " ~ user.name | trim }} {% endautoescape %}" This way, "Hello World" is rendered to "Hello World" and the twig compiler will remove any whitespace on the left and right side. ## Caveats When using Twig inside a Phalcon application, the following restrictions apply: * Phalcon must be the first extension loaded; the Twig() constructor will always return a fatal error. * To be able to access the Phalcon internals, the 'PhalconDI\Injector' and 'PhalconDI\FactoryDefault' namespaces should be either be auto-registered or explicitly registered; the Twig() constructor will return an error if this doesn't happen. * You cannot define templates in an autoloading loader, as they must be defined with a name and extension (e.g., 'myapp/templates/index.twig'). * You cannot register any Twig extensions that include the "twig" framework dependency (e.g., Twig\TwigFilter or Twig\TwigFilterInterface), as they are included by this package. * To define custom extensions, you need to explicitly reference the compiled version found in the 'vendor/twig/82157476af'
